Celiac Disease

Celiac Disease Facts

- **Affects ~ 1% of the USA population***
- **2-3 million cases in the USA**
- **5-20 affected children in average practice**
- **~ 80% undiagnosed**

***Arch Int Med 2003;163:286-92**

- Med 2003;163:286-92

Celiac Disease Learning Objectives

Identify children in need of testing for celiac disease

Choose most effective serological tests for screening

Understand the need to confirm the diagnosis before treating.

Celiac Disease Guidelines: 2004-2013

Abstract

BACKGROUND & AIMS: The European Society for Pediatric Gastroenterology and Nutrition proposed guidelines for the **diagnosis** of **celiac disease**, stating that duodenal biopsy is no longer needed if patients have symptoms and **levels** of immunoglobulin A anti-tissue transglutaminase (IgA anti-tTG) more than 10-fold the cutoff value. We evaluated the accuracy of this guideline in a well-characterized population using different commercial assays.

METHODS: We analyzed **levels** of IgA anti-tTG in serum samples from 104 consecutive pediatric and adult patients who were not deficient in IgA and diagnosed with **celiac disease** from August 1, 2000 to December 31, 2009. We also analyzed serum samples from 537 consecutive patients without **celiac disease** (controls), collected from May 1, 2004 to October 12, 2006, who underwent intestinal biopsy analysis. Serum **levels** of antibodies were quantified using assays from BioRad, INOVA, Genesis, and Thermo Fisher.

RESULTS: The likelihood ratio (probability of a specific result in patients divided by probability of the same result in controls) for **celiac disease** increased with **levels** of IgA anti-tTG in all assays. Depending on the assay, the likelihood ratio for **levels** >10-fold the cutoff ranged from 111 to 294. The percentage of patients with **celiac disease** with **levels** of IgA anti-tTG>10-fold the cutoff ranged from 41% to 61%, depending on the assay. For **levels** of anti-tTG>10-fold the cutoff, the post-test probabilities for **celiac disease** (probability of **disease**, based on pre-test probability and test result) were, depending on the assay, 89%-96% and 53%-75% (depending on the assay), for pre-test probabilities (probability of **disease** depending on symptoms) of 7% and 1%, respectively.

CONCLUSIONS: To **diagnosis celiac disease** based on serologic factors, it might be best to define **thresholds** for **levels** of IgA anti-tTG based on a predefined likelihood ratio or post-test probability, instead of a multiple of a cutoff value. Patients with a high pre-test probability and **levels** of anti-tTG >10-fold the cutoff have a high probability for having **celiac disease**, aiding clinical decision making.

SHORT COMMUNICATION

ESPGHAN Guidance on Coeliac Disease 2012: Multiples of ULN for Decision Making Do Not Harmonise Assay Performance Across Centres

*William Egner, †Anna Shrimpton, †Ravishankar Sargur, *Dina Patel, and †Kirsty Swallow

ABSTRACT

The updated ESPGHAN guidance on coeliac disease recommends the use of common multiples of the upper limit of normal (ULN) for IgA tissue transglutaminase antibodies (TG2) when deciding which diagnostic pathway to follow. The current lack of standardisation between assays makes it difficult to harmonise results between centres as different performance characteristics are observed with each assay. This variability is shown in data from external quality assessment distributions. As a result, the updated guidance is too generalised for use with all the commercial TG2 kits and is therefore not translatable for use in all centres.

Key Words: coeliac disease, ESPGHAN guidelines, tissue transglutaminase antibodies

(*JPGN* 2012;55: 733–735)

use of titres in its diagnostic algorithms and conflicts with the external quality assessment (EQA) data used. Lack of standardisation (full metrological traceability) of assays has not been ignored, but unfortunately the wrong approach has been used to try to compensate by harmonisation (by using the same units even where there is little metrological traceability).

Use of common ULN risks different centres getting very different screening results when using different assays, and therefore following a different pathway through the algorithm for the same patient. This has the potential to lead to some centres making different biopsy requests depending on the assay used, despite the guidelines intention of avoiding biopsy in those who screen strongly positive for TG2. Furthermore, it is not yet clear that the PPV of high titres is the same for all assays even where they produce similar apparent results for the mean or median ULN.

Presentation of Celiac Disease in Adults

Sheryl Pfeil, MD
Associate Professor – Clinical
Department of Internal Medicine
Division of Gastroenterology, Hepatology & Nutrition
The Ohio State University Wexner Medical Center

Presentation of Celiac Disease in Adults

- Delay in diagnosis common ("celiac iceberg")
- May be diagnosed at any age
- No weight exclusion
- Geographically widespread

Presentation of Celiac Disease in Adults

- Frequent cause of unexplained iron deficiency
- GI symptoms: diarrhea, bloating, "IBS" type symptoms
- Spectrum of severity and symptoms; majority have mild symptoms; mono- or oligosymptomatic
- Non-GI manifestations and celiac associated conditions

Celiac Disease and Iron Deficiency in Adults

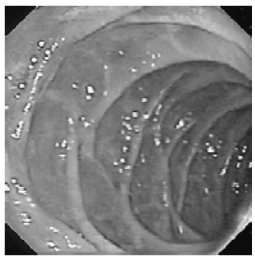
- 5-8% of adults with unexplained iron deficiency anemia have CD
- Many patients undergoing EGD for anemia do not get duodenal biopsies
- Macroscopic and microscopic findings
- Biopsy duodenal bulb and descending duodenum

(2 + 4)

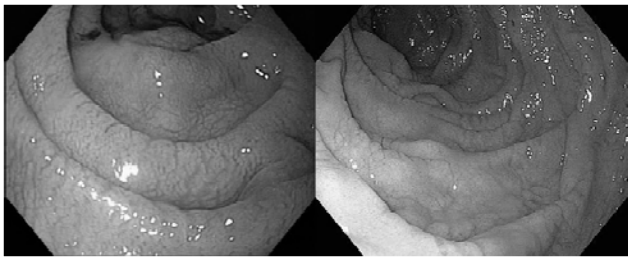
Endoscopic "Clues" in Diagnosis of Celiac Disease

- Loss of duodenal folds
- Fissuring or scalloping along folds
- Nodularity
- Mosaic pattern

Endoscopic "Clues" in Diagnosis of Celiac Disease

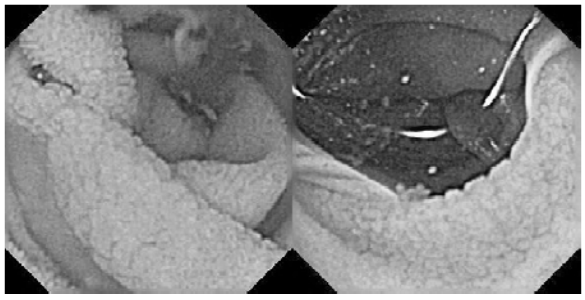


Normal Duodenum



Celiac Disease

Endoscopic "Clues" in Diagnosis of Celiac Disease



Capsule Endoscopy in Celiac Disease

Microscopic Diagnosis of Celiac Disease

- Spectrum of change
- "False positive" biopsies (NSAIDs, olmesartan, tropical sprue, autoimmune enteropathy, self-limited enteritis, Crohn's)
- Correlate with serologies and HLA type

Abnormal Liver Tests and Celiac Disease

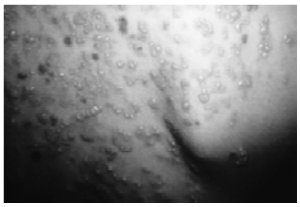
- Incidental elevated transaminases (ALT, AST): up to 9% may have “silent” celiac disease
- Non-specific reactive hepatitis
- Liver tests normalize on a gluten free diet
- Other associated autoimmune liver disorders
  - Primary biliary cirrhosis
  - Autoimmune hepatitis

Conditions Associated with Celiac Disease in Adults

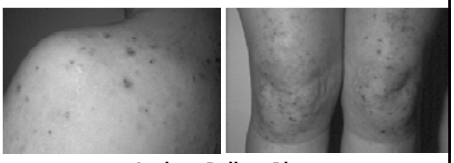
- Dermatitis herpetiformis
- Cerebellar ataxia
- Arthralgias
- Osteoporosis
- Reproductive disorders
- Small bowel malignancies (lymphoma and adenocarcinoma)

Dermatitis Herpetiformis

- Symmetric pruritic papules and vesicles on forearms, knees, buttocks
- Majority (90%) no GI symptoms
- Majority (75+% have increased IEL's or villous atrophy)
- Gluten sensitive
- Responds to gluten withdrawal



CDC



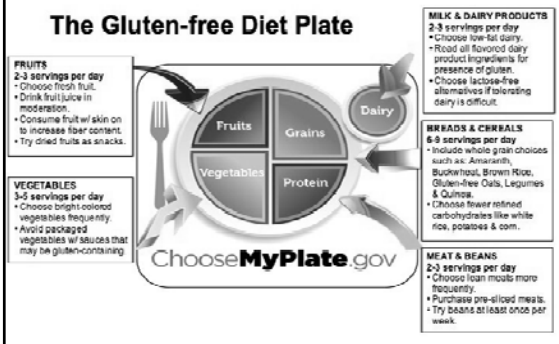
Author: BallenaBlanca

Osteopenia and Osteoporosis

- Early fractures often without GI symptoms
- Secondary hyperparathyroidism due to vitamin D deficiency
- Peripheral > axial bone loss
- Partial reversal on gluten free diet
- Perform DXA scan at diagnosis

Treatment of Celiac Disease

Author: Gérard Lorenz



- Gluten free diet
- Dietician referral
- Motivation: reduced complications
- Explosion of gluten free food industry

Author: DryPot

Early Management of the Adult Celiac Patient

- Confirm diagnosis before treatment
- Diet instruction and support
  - Gluten free diet for life
  - Avoid wheat, barley, and rye
- Test for (and correct) nutrient deficiencies
- DXA scan to evaluate for bone loss

Early Management of the Adult Celiac Patient

- Follow response to therapy
- Recheck serology (if initially positive)
- Support group

Late Management of the Adult Celiac Patient

- **Annual visit**
- **Repeat DXA scan (and vitamin D testing) depending on initial results**
- **May check serology (if initially positive) and routine labs (CBC, metabolic panel)**
- **Symptom flare: think inadvertent gluten ingestion, microscopic colitis, less likely malignancy**

Celiac Disease Dilemmas

- **Self-imposed gluten free diet - confounds diagnostic testing (except HLA type)**
- **The patient who will not eat gluten**
  - **OK if nutritionally sound**
- **"Diagnosis" on basis of single positive test (e.g. gliadin antibodies, HLA type)**
- **Gluten "sensitivity"**

Summary Points

- **Test before treating**
- **You won't find what you don't look for: associated conditions and endoscopic findings**
- **Use the best serology strategy (Ig A anti-tTG Ab) if not Ig A deficient**

Summary Points

- **Recognize risk groups and remember iron deficient anemia**
- **Diet "cures" the manifestations of the disease**
- **Follow the patient**
